Project Description

This project implements a web-based document management and search system that allows users to upload documents (PDF and Word), extract their textual content, store it in Elasticsearch, and perform full-text and partial searches with highlighted results.

The system provides a REST API and a simple web interface where users can:

- Upload documents
- View list uploaded documents
- Delete documents
- Search inside document content using single or multiple terms
- View highlighted matches inside documents

Elasticsearch is used as the search engine, while Apache Tika is used for text extraction from documents. The backend is implemented using Spring Boot (Java).

List of Use Cases

UC1 – Upload Document

- Description: The user uploads a PDF or Word document.
- Result: The document content is extracted and indexed in Elasticsearch.

UC2 – List Documents

- Description: The user requests a list of all uploaded documents.
- Result: The system returns document IDs and filenames.

UC3 – View Document Content

- Description: The user selects a document.
- Result: The full extracted content of the document is displayed.

UC4 – Search in Document Content

- Description: The user searches using one or multiple keywords.
- Result: Matching document fragments are returned with highlighted terms.

UC5 – Delete Document

- Description: The user deletes a document.

- Result: The document is removed from Elasticsearch.

Elasticsearch Mapping

Mapping used in the project

Index: documents

PUT documents

```
{  
  "mappings": {  
    "properties": {  
      "filename": { "type": "keyword" },  
      "content": { "type": "text" },  
      "file_type": { "type": "keyword" },  
      "word_count": { "type": "integer" },  
      "upload_date": { "type": "date" }  
    }  
  }  
}
```

Implementation description

Backend

- Implemented using Spring Boot
- REST APIs handle: upload document, get list of all documents, view content of document, search in the content of a document, delete document

Text Extraction

- Apache Tika extracts content from PDF and Word documents
- Extracted text is indexed into Elasticsearch

Search

- Supports: Partial search, Multi-term search
- Elasticsearch highlights matched terms

Frontend

- HTML + JavaScript UI
- Sidebar displays documents
- Clicking search results opens the correct document with highlight

API Documentation – Swagger

APIs used are documented in swagger:

| | | |
|--|--|---|
| Upload API API for uploading PDF and Word documents | | ^ |
| POST | /upload Upload a document | ▼ |
| Documents API APIs for managing and searching documents stored in Elasticsearch | | ^ |
| GET | /search Search in document content | ▼ |
| GET | /documents Get all documents | ▼ |
| GET | /documents/{id} Get document content by ID | ▼ |
| DELETE | /documents/{id} Delete document by ID | ▼ |

Postman Testing

Collection of Postman was created to test the APIs:

The screenshot displays the Postman application interface. On the left sidebar, the 'My Workspace' section is active, showing a collection named 'DocumentContentSearch' with a 'POST Upload document' endpoint. The main workspace shows the details of this endpoint, including the URL 'http://localhost:8080/upload' and the method 'POST'. The 'Body' tab is selected, showing a 'form-data' type with a single key-value pair: 'file' with the value 'Document Content Search using Elasticsearch.docx'. The 'Test Results' section at the bottom shows a successful response with a status of '200 OK', a response time of '145 ms', and a body of '257 B'. The response body is displayed in JSON format:

```
{
  "filename": "Document Content Search using Elasticsearch.docx",
  "message": "upload successful"
}
```
